Hong Kong SAR, China

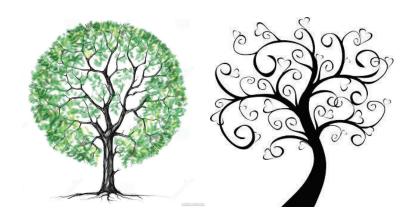

Rm 3553, desmond@ust.hk

OMP 2012H (Fall 2020)

1 / 44

Part I

Tree Data Structure

Rm 3553, desmond@ust.hk

COMP 2012H (Fall 2020

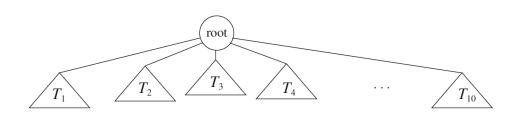

.

Tree

- The linear access time of linked lists is prohibitive for large amount of data.
- Does there exist any simple data structure for which the average running time of most operations (search, insert, delete) is better than linear time?
- Solution: Trees!
- We are going to talk about
 - ► basic concepts of trees
 - tree traversal
 - ► (general) binary trees
 - binary search trees (BST)
 - ► balanced trees (AVL tree)

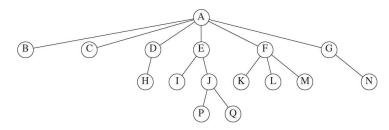

Recursive Definition of Trees

A tree T is a collection of nodes connected by edges.

- base case: T is empty
- recursive definition: If not empty, a tree T consists of
 - ► a root node *r*, and
 - ightharpoonup zero or more non-empty sub-trees: T_1, T_2, \ldots, T_k

Tree Terminologies

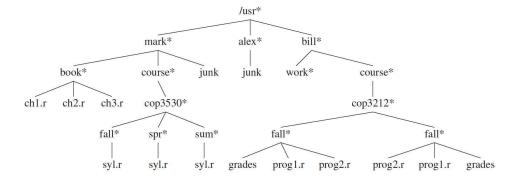

- Root: the only node with no parents
- Parent and child
 - every node except the root has exactly only 1 parent
 - ▶ a node can have zero or more children
- Leaves: nodes with no children
- Siblings: nodes with the same parent
- Path from node n_1 to n_k : a sequence of nodes $\{n_1, n_2, \dots, n_k\}$ such that n_i is the parent of n_{i+1} for $1 \le i \le k-1$.

Rm 3553, desmond@ust.hk

COMP 2012H (Fall 2020

5 / 44

Example 1: Unix Directories in a Tree Structure

Tree Terminologies ..

- Length of a path
 - number of edges on the path
- Depth of a node
 - length of the unique path from the root to that node
- Height of a node
 - length of the longest path from that node to a leaf
 - all leaves are at height 0
- Height of a tree
 - = height of the root
 - = depth of the deepest leaf
- Ancestor and descendant: If there is a path from n_1 to n_2
 - n1 is an ancestor of n2
 - n2 is a descendant of n1
 - if $n1 \neq n2$, proper ancestor and proper descendant

COMP 2012H (Fall 2020

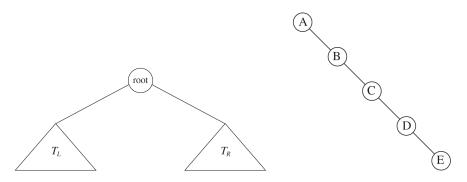

6/4

Part II

Binary Tree

Binary Trees

- Generic binary tree: A tree in which no node can have more than two children.
- The height of an 'average' binary tree with N nodes is considerably smaller than N.
- ullet In the best case, a well-balanced tree has a height of order of $log\ N$.
- But, in the worst case, the height can be as large as (N-1).

Binary Tree: Inorder Traversal

A Typical Implementation of Binary Tree ADT

```
/* File: btree.h */
#include <iostream>
using namespace std;
template <class T> class BTnode
  public:
    BTnode(const T& x, BTnode* L = nullptr, BTnode* R = nullptr)
      : data(x), left(L), right(R) { }
    ~BTnode()
        delete left;
        delete right;
        cout << "delete the node with data = " << data << endl;</pre>
    const T& get_data() const { return data; }
    BTnode* get_left() const { return left; }
    BTnode* get_right() const { return right; }
  private:
    T data;
                        // Stored information
    BTnode* left;
                        // Left child
    BTnode* right;
                        // Right child
};
```

Example 2: Binary Tree Creation & Traversal

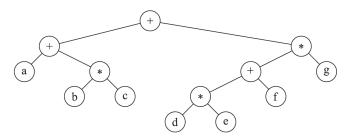

```
/* File: test-btree.cpp */
#include "btree.h"
#include "btree-preorder.cpp"
#include "btree-inorder.cpp"
#include "btree-postorder.cpp"
template <typename T>
void print(BTnode<T>* root) { cout << root->get_data() << endl; }</pre>
int main() // Build the tree from bottom up
{ // Create the left subtree
    BTnode<int>* node5 = new BTnode<int>(5):
    BTnode<int>* node9 = new BTnode<int>(9);
    BTnode<int>* node8 = new BTnode<int>(8, node5, node9);
    // Create the right subtree
    BTnode<int>* node12 = new BTnode<int>(12);
    BTnode<int>* node17 = new BTnode<int>(17);
    BTnode<int>* node15 = new BTnode<int>(15, node12, node17);
    // Create the root node
    BTnode<int>* root = new BTnode<int>(10, node8, node15);
    cout << "\nInorder traversal result:\n"; btree_inorder(root, print);</pre>
    cout << "\nPreorder traversal result:\n"; btree_preorder(root, print);</pre>
    cout << "\nPostorder traversal result:\n"; btree_postorder(root, print);</pre>
    cout << "\nDeleting the binary tree ...\n"; delete root; return 0;</pre>
```

Rm 3553, desmond@ust.h

MP 2012H (Fall 2020

14/44

Example 4: Expression (Binary) Trees

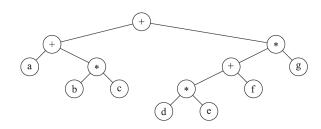

• Above is the tree representation of the expression:

$$(a + b * c) + ((d * e + f) * g)$$

- Leaves are operands (constants or variables).
- Internal nodes are operators.
- The operators must be either unary or binary.

Rm 3553, desmond@ust.hk COMP 2012H (Fall 2020) 15 / 44 Rm 3553, desmond@ust.hk COMP 2012H (Fall 2020)

Expression Tree: Different Notations

- Preorder traversal: node, left sub-tree, right sub-tree.
 - \Rightarrow Prefix notation: + + a * bc * + * defg
- Inorder traversal: left sub-tree, node, right sub-tree.
 - \Rightarrow Infix notation: a + b * c + d * e + f * g
- Postorder traversal: left sub-tree, right sub-tree, node.
 - \Rightarrow Postfix notation: abc*+de*f+g*+

19 / 44

Part III

Binary Search Tree (BST)

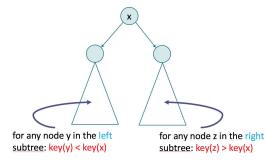

Rm 3553, desmond@ust.hk

COMP 2012H (Fall 2020)

18 / 44

Properties of a Binary Search Tree

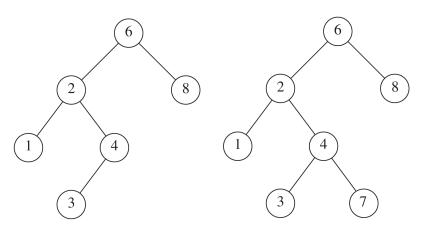

- BST is a data structure for efficient searching, insertion and deletion.
- BST property: For every node *x*
- All the keys in its left sub-tree are smaller than the key value in node x.
- All the keys in its right sub-tree are larger than the key value in node x.

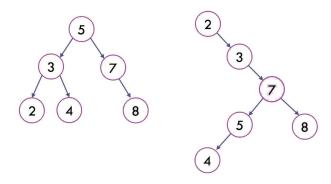

BST Example and Counter-Example

BST

Not a BST but a Binary Tree

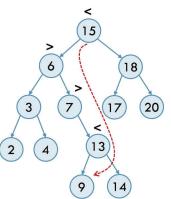

BSTs May Not be Unique

- The same set of values may be stored in different BSTs.
- Average depth of a node on a BST is order of log N.
- Maximum depth of a node on a BST is order of N.

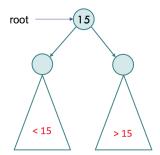

Example 5: BST Search

• Let's search for the value 9 in the following BST.

Compare	Action
9 vs. 15	continue with the left subtree
9 vs. 6	continue with the right subtree
9 vs. 7	continue with the right subtree
9 vs. 13	continue with the left subtree
9 vs. 9	eureka!

BST Search

For the above BST, if we search for a value

- of 15. we are done at the root.
- < 15, we would recursively search it with the left sub-tree.
- \bullet > 15, we would recursively search it with the right sub-tree.

Rm 3553, desmond@ust.hk

Our BST Implementation (different from textbook's) I

```
template <typename T> class BST /* File: bst.h */
 private:
    struct BSTnode
                        // A node in a binary search tree
     T value;
                       // Left sub-tree or called left child
     BST left;
                       // Right sub-tree or called right child
     BST right;
     BSTnode(const T& x) : value(x) \{\ \} // A copy constructor for T
     // BSTnode(const T& x) : value(x), left(), right() { } // Equivalent
     BSTnode(const BSTnode& node) = default; // Copy constructor
     // BSTnode(const BSTnode& node)
                                              // Equivalent
             : value(node.value), left(node.left), right(node.right) { }
      "BSTnode() { cout << "delete: " << value << endl; }
    BSTnode* root = nullptr;
 public:
   BST() = default;
                               // Empty BST
    "BST() { delete root; }
                               // Actually recursive
```

Our BST Implementation (different from textbook's) II

```
// Shallow BST copy using move constructor
    BST(BST&& bst) { root = bst.root; bst.root = nullptr; }
    BST(const BST& bst) // Deep copy using copy constructor
        if (bst.is_empty())
            return;
        root = new BSTnode(*bst.root); // Recursive
    bool is_empty() const { return root == nullptr; }
    bool contains(const T& x) const;
    void print(int depth = 0) const;
    const T& find max() const; // Find the maximum value
    const T& find_min() const; // Find the minimum value
    void insert(const T&);
                               // Insert an item with a policy
    void remove(const T&):
                               // Remove an item
};
```

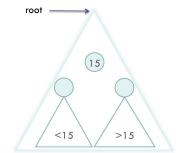

Rm 3553, desmond@ust.hk

COMP 2012H (Fall 2020)

25 / 44

Our BST Implementation

- Our implementation really implements a BST as an object.
- It has a root pointing to a BST node which has
 - a value (of any type)
 - a left BST object: a sub-tree with values smaller than that of the root.
 - a right BST object: a sub-tree with values greater than that of the root.

Rm 3553, desmond@ust.hl

COMP 2012H (Fall 2020

Rm 3553, desmond@ust.hl

}

return node->value;

* Return: The min value

COMP 2012H (Fall 2020

00/11

BST Code: Find the Maximum Stored Value

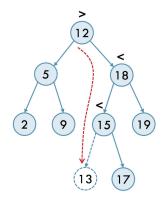

BST Code: Find the Minimum Stored Value

/* Goal: To find the min value stored in a non-empty BST.

* Remark: The min value is stored in the leftmost node.

BST: Insert a Node of Value x

node = node->left.root:

- E.g., insert 13 to the BST.
- Proceed down the tree as you would with a search.
- If x is found, do nothing (or update something).
- Otherwise, insert x at the last spot on the path traversed.
- Time complexity = Order of (height of the tree)

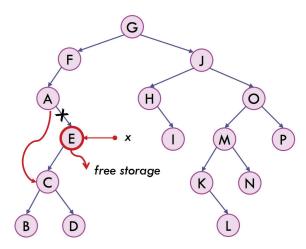

BST Code: Insertion

Rm 3553. desmond@ust.hk

OMP 2012H (Fall 2020)

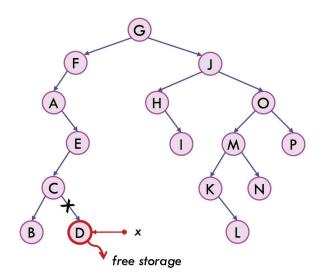

33 / 44

BST: Delete a Node with 1 Child

• Adjust a pointer from its parent to bypass the deleted node.

BST: Delete a Leaf

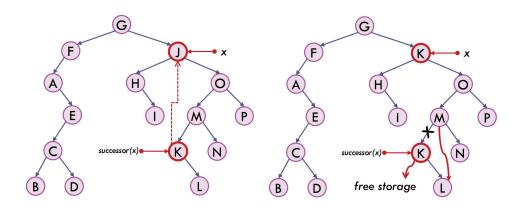

• Delete the leaf node immediately.

Rm 3553, desmond@ust.hl

OMP 2012H (Fall 2020

34 / 44

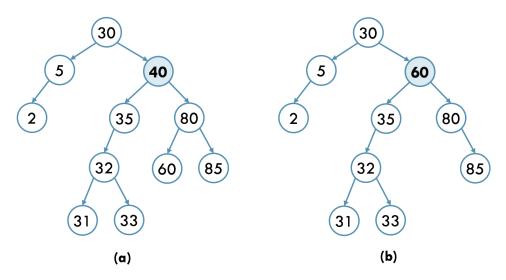

BST: Delete a Node with 2 Children

- You will have 2 choices: replace the deleted node with the
 - maximum node in its left sub-tree, or
 - minimum node in its right sub-tree (as in the above figure).
- Remove the max/min node depending on the choice above.

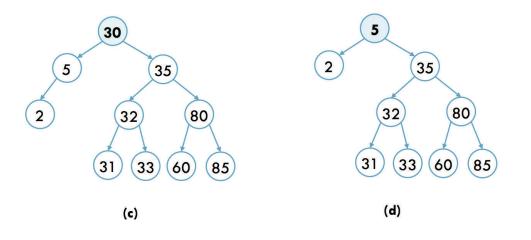

Example 6.1: BST Deletions

• Removing 40 from BST(a), replacing it with the min. value in its right sub-tree results in the BST(b).

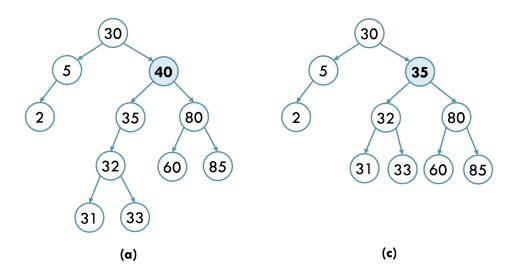

Example 6.3: BST Deletions

• Removing 30 from BST(c) and moving 5 from its left sub-tree result in BST(d).

Example 6.2: BST Deletions

• Removing 40 from BST(a), replacing it with the max. value in its left sub-tree results in the BST(c).

BST Code: Deletion

```
template <typename T>
                                /* File: bst-remove.cpp */
void BST<T>::remove(const T& x) // leftmost item of its right subtree
   if (is_empty())
                                // Item is not found; do nothing
       return;
    if (x < root->value)
                                // Remove from the left subtree
        root->left.remove(x);
    else if (x > root->value)
                               // Remove from the right subtree
        root->right.remove(x);
    else if (root->left.root && root->right.root) // Found node has 2 children
       root->value = root->right.find_min(); // operator= defined?
       root->right.remove(root->value); // min is copied; can be deleted now
   else
                                // Found node has 0 or 1 child
        BSTnode* deleting_node = root; // Save the root to delete first
       root = (root->left.is_empty()) ? root->right.root : root->left.root;
       // Set subtrees to nullptr before removal due to recursive destructor
       deleting_node->left.root = deleting_node->right.root = nullptr;
        delete deleting_node;
```
